## DECLARATION BY THE CANDIDATE

We **K Harshini, V Vaishnavi**, **C Divya Tejaswi** bearing Roll Nos. **22R11A05F8, 22R11A05J3, 22R11A05E7**, hereby declare that the project report entitled **"Smart ID Card Using IOT for Real-Time Location"** is done under the guidance of **Dr. A. Hari Prasad Reddy, Professor** Department of Computer Science and Engineering, Geethanjali College of Engineering and Technology, is submitted in partial fulfillment of the requirements for the award of the degree of **Bachelor of Technology in Computer Science and Engineering**.

This is a record of bonafide work carried out by me/us and the results embodied in this project have not been reproduced or copied from any source. The results embodied in this project report have not been submitted to any other University or Institute for the award of any other degree or diploma.

**K Harshini (22R11A05F8)**
**V Vaishnavi (22R11A05J3)**
**C Divya Tejaswi(22R11A05E7)**
**Department of CSE,**
**Geethanjali College of Engineering and Technology,**
**Cheeryal.**

# ACKNOWLEDGEMENT

It is with profound gratitude and sincere appreciation that We extend my heartfelt thanks to all those who have played a significant role in the successful completion of this undergraduate project.

First and foremost, We express our deep sense of respect and gratitude to our **Honourable Chairman, Mr. G. R. Ravinder Reddy**, for his constant encouragement and for nurturing a culture of academic excellence and innovation within the institution.

We would also like to express our sincere thanks to **Dr. S. Udaya Kumar**, **Director**, for his visionary leadership and continued support, which have provided the ideal environment and motivation for academic pursuits such as this project.

Our heartfelt appreciation goes to **Dr. K. Sagar**, **Principal,** for his steadfast guidance, infrastructural support, and encouragement that have helped bring this project to successful fruition.

We are deeply grateful to **Dr. E. Ravindra, Professor**, **Head of the Department- CSE**, for his academic leadership, valuable feedback, and continuous support throughout the duration of this project.

We extend my sincere thanks to our **Project Coordinators, Dr.S. Durga Prasad, Mrs. M. Viswaa Shanthi** for their meticulous planning, timely evaluations, and constant coordination that ensured a smooth and structured project development process.

A special note of gratitude is reserved for my project guide, **Dr. A. Hari Prasad Reddy, Professor**, whose expert supervision, insightful suggestions, and dedicated mentorship have been instrumental in shaping the direction and outcome of this work.

Lastly, We are ever grateful to our **parents and family** for their unconditional love, encouragement, and moral support. Their faith in us has been our greatest strength throughout this journey.

With genuine appreciation, We acknowledge every individual who has, in one way or another, contributed to the successful completion of this project.

**With warm regards,**
**K Harshini, V Vaishnavi, C Divya Tejaswi**
**22R11A05F8, 22R11A05J3, 22R11A05E7**

**Geethanjali College of Engineering and Technology**

# ABSTRACT

In today's rapidly evolving world, ensuring the safety, accountability, and real-time tracking of individuals has become an essential requirement in both educational institutions and professional workplaces. Traditional identification systems provide limited functionality, often restricted to static authentication and attendance logging. To overcome these limitations, this project introduces a Smart ID Card System using Internet of Things (IoT) technology, designed to enable real-time location tracking, geofencing-based alerts, and web-based monitoring of students or employees.

The proposed system is built around the ESP8266 NodeMCU microcontroller, which acts as the core processing and communication unit. It integrates a Neo-6M GPS module to obtain accurate live geographical coordinates of the individual carrying the Smart ID card. Using these coordinates, the system continuously monitors the person's location relative to a predefined geofenced boundary. Whenever the individual crosses this boundary, the system automatically triggers an SMS alert to authorized personnel (such as administrators or security officers), ensuring immediate awareness and action.

To maintain reliable time accuracy and consistency across devices, the project employs Network Time Protocol (NTP) for real-time clock synchronization. Furthermore, an interactive web dashboard has been developed using the ESP8266 WebServer functionality, allowing administrators to visualize live GPS data, track location history, and observe satellite signal strength. The dashboard utilizes Leaflet.js, an open-source JavaScript library, to render real-time map visualizations with geofence boundaries and status indicators.

By leveraging IoT, GPS, and web technologies, the proposed Smart ID Card enhances both security and operational efficiency. It represents a step forward in developing smart, connected identification systems that contribute to a safer, more responsive, and technologically empowered environment.

# Chapter 1 Introduction

## 1.1 Overview of the Project

The Smart ID Card using IoT project is designed to provide a real-time location tracking solution for institutions and workplaces. It integrates ESP8266 NodeMCU, Neo-6M GPS, and SIM900A GSM modules to monitor the position of an individual and send alerts when they move out of a predefined area. The system uses the TinyGPS++ library to process GPS data, and the ESP8266 WebServer hosts a web dashboard for live visualization.

This project combines IoT, GPS, and GSM technologies to offer real-time monitoring, automatic alerts, and enhanced security. The web interface, built using Leaflet.js, displays live coordinates and geofence status, allowing administrators to ensure safety and transparency. It provides a cost-effective and scalable approach for tracking and managing individuals in schools, offices, and secure zones.

## 1.2 Problem Statement

Many institutions and industries struggle to track movement and ensure the safety of students, employees, or field workers efficiently. Manual attendance systems or surveillance methods are often time-consuming, unreliable, and prone to human error, leading to inaccurate monitoring and delayed response to boundary violations.

To overcome these limitations, there is a need for a smart, automated, and low-cost IoT-based solution that can detect real-time movement and send alerts instantly. The proposed system offers continuous location tracking, geofence detection, and SMS notification, reducing manual intervention and improving monitoring accuracy.

## 1.3 Objectives

- To develop a portable smart ID system using ESP8266**,** GPS, and GSM modules for location tracking.
- To design a real-time web interface for displaying live location, coordinates, and geofence status.

- To send automatic SMS alerts to administrators when a user moves outside the predefined area.
- To implement accurate time synchronization using NTP servers for reliable event logging.
- To create a secure, efficient, and scalable IoT-based tracking framework suitable for multiple environments.

## 1.4 Scope

The Smart ID Card system can be deployed in schools, colleges, offices, hospitals, and restricted zones to track authorized individuals efficiently. It helps administrators improve security, manage attendance, and ensure safety by monitoring personnel within designated areas.

Additionally, the project concept can be extended to smart campuses, logistics, defense systems, and asset tracking. Its modular design allows easy scaling and future upgrades, including cloud storage and mobile app integration, making it a versatile and practical IoT application.

## 1.5 SDLC Model

The project follows the Agile Software Development Life Cycle (SDLC) model, which focuses on iterative development and continuous improvement. This approach is ideal for IoT systems, where hardware and software components require frequent integration and testing.

Each iteration in Agile includes requirement analysis, design, development, testing, and feedback, allowing flexibility and adaptability during implementation. This ensures that the system evolves smoothly, delivering a reliable and efficient final product suitable for real-world IoT applications.

# Chapter 2 Literature Survey

## 2.1 Review of Existing Systems

Existing tracking systems mainly use GPS and mobile applications that rely on constant internet connectivity and cloud storage. These systems can provide accurate location data but often face limitations when there is poor network coverage or device battery issues. They are also highly dependent on external servers, which may increase data security risks.

On the other hand, standalone GSM-based trackers send location information via SMS without requiring the internet. While this approach ensures basic functionality in offline areas, it lacks an interactive interface or live visualization of the tracked person or object. Therefore, most existing systems are either too dependent on the internet or too limited in functionality for real-time institutional or workplace tracking.

## 2.2 Limitations of Existing Systems

- The main drawback of current tracking systems is their dependence on continuous mobile networks or cloud servers. This makes them unreliable in areas with weak signals or during network failures. They also tend to consume more power and require high maintenance due to their connectivity needs.
- Additionally, most systems do not offer local dashboards for monitoring, which limits user interaction and visualization of data. Accuracy issues in geofence detection, higher operational costs, and lack of integration between different communication modules further reduce their efficiency and practicality.

## 2.3 Need for the Proposed System

There is a growing need for a compact and reliable IoT-based system that combines GPS, GSM, and Wi-Fi technologies to support both online and offline tracking. Such a system can provide continuous monitoring, even when one form of connectivity fails, ensuring seamless performance.

The proposed Smart ID Card System aims to meet this demand by integrating multiple modules for better accuracy and communication. It can send SMS alerts in offline mode and sync data to a web dashboard when Wi-Fi becomes available, ensuring efficiency, reliability, and cost-effectiveness.

## 2.4 Comparative Study

| System | Connectivity | Alert Type | Cost | Visualization |
|---|---|---|---|---|
| Mobile App GPS | Internet | Push Notification | High | App only |
| GSM Tracker | GSM | SMS | Medium | No |
| **Proposed System** | GSM + Wi-Fi | SMS + Web | Low | Yes |

**Table 2.4 Comparative study**

## 2.5 Summary

In summary, the study of existing systems highlights the challenges of dependency, high cost, and lack of visualization in traditional GPS and GSM trackers. They are often unsuitable for real-time and large-scale applications due to connectivity and usability constraints.

The proposed Smart ID Card System overcomes these limitations through IoT integration, enabling accurate tracking, geofence-based alerts, and web monitoring. It bridges the gap between local IoT-based systems and modern cloud-based trackers, providing a reliable and efficient solution.

# Chapter 3 System Analysis

## 3.1 Feasibility Study

The Smart ID Card using IoT project is technically feasible because it uses Arduino-compatible components like the ESP8266 NodeMCU, SIM900A GSM module, and Neo-6M GPS module. These components are easy to program using the Arduino IDE and require minimal power to operate. The modules communicate efficiently and support real-time data transfer, making them suitable for a compact IoT tracking system.

From an economic perspective, the system is low-cost, with a total budget under ₹1500, making it affordable for institutions and small organizations. Operationally, it is simple to use and requires minimal configuration. Once powered on, it automatically tracks location, detects boundary violations, and sends SMS alerts, ensuring reliable and smooth operation without the need for complex maintenance.

## 3.2 Hardware and Software Requirements

The hardware components form the foundation of the system. The ESP8266 NodeMCU acts as the central controller that connects the GPS and GSM modules. The Neo-6M GPS module provides accurate coordinates, while the SIM900A GSM module sends alert messages when the user exits the geofence. Additional components like jumper wires and a 5V power source support circuit connectivity and power distribution.

The software components include the Arduino IDE for code development and uploading to the ESP8266. The TinyGPS++ library helps decode GPS data, and the ESP8266WiFi library enables wireless communication. The Leaflet.js library is used for displaying the real-time map and geofence area on a web dashboard. Together, these tools ensure efficient data processing and visualization.

## 3.3 Functional and Non-Functional Requirements

The functional requirements define the main operations of the system. The Smart ID Card must continuously track the user's live location, detect when they cross a predefined boundary, and send an SMS alert through the GSM module.

The non-functional requirements ensure system performance and reliability. The system must operate with low latency, provide accurate and timely alerts, and be easy to use with minimal setup. It should also be scalable, allowing integration with additional modules or cloud platforms in the future, while maintaining energy efficiency for portable use.

# Chapter 4 System Design

## 4.1 System Architecture

The system architecture of the IoT-based Geo-Fence Tracker is designed to provide continuous real-time tracking and instant alerts when a monitored object moves beyond a predefined boundary. The architecture integrates hardware components (GPS, GSM, microcontroller) with software modules (geofencing logic, dashboard interface, and alert system) into a single cohesive IoT solution.

### 4.1.1 Overview

The system functions as a closed loop where the GPS module detects the object's position, the ESP8266 NodeMCU processes the data and evaluates whether the object is inside the virtual boundary, and the SIM900A GSM module sends an SMS alert if a violation occurs. Meanwhile, a browser dashboard hosted by the ESP8266 displays the location in real time on a map.

This architecture is optimized for low latency, low power consumption, and high reliability while maintaining simplicity and scalability for future enhancements.

### 4.1.2 Component-wise Description

1. **GPS Module (Neo-6M):**
    a. The GPS receiver communicates with satellites orbiting the Earth to calculate the device's precise position in terms of latitude, longitude, altitude, and time (UTC).
    b. It uses the NMEA protocol to transmit data strings such as $GPRMC and $GPGGA to the microcontroller via UART serial communication.
    c. The module outputs updated coordinates every second (1 Hz), ensuring near real-time tracking.
    d. In case of signal loss (e.g., indoor or obstructed areas), fallback coordinates or last-known position are used to maintain system continuity.
2. **ESP8266 NodeMCU (Microcontroller + Wi-Fi Processor):**
    a. Acts as the central controller responsible for data acquisition, processing, and communication.

b. It receives GPS data, applies the Point-in-Polygon (PIP) algorithm to verify if the current location lies inside or outside the geofence, and initiates alerts if necessary.
c. The ESP8266 also runs an embedded HTTP web server that serves the live dashboard interface.
d. Through its integrated Wi-Fi, it enables the user's browser to connect directly to the device and visualize movement in real time.

3. **SIM900A GSM Module:**
   a. This module enables the system to communicate over the GSM cellular network by sending SMS alerts to registered users.
   b. Controlled using standard AT commands, it operates in text mode (AT+CMGF=1) for simple message transmission.
   c. When the ESP8266 detects that the GPS location has crossed the virtual boundary, it sends an alert containing the coordinates, timestamp, and a custom warning message.
   d. The GSM module ensures that alerts are delivered even in the absence of Wi-Fi or internet, providing redundancy.
4. **Browser-Based Web Dashboard:**
   a. The front-end dashboard, hosted on the ESP8266, provides users with a simple yet powerful interface for visual tracking.
   b. It uses Leaflet.js, a lightweight open-source JavaScript library, to render maps and markers.
   c. The interface fetches new coordinates every 2 seconds via AJAX requests to the /values API endpoint.
   d. Color-coded indicators (green = inside fence, red = outside) visually show the system's status.
   e. Additional textual information such as current coordinates, fence status, and last update time are also displayed.
5. **Power Supply Unit:**
   a. The system operates on a 5V regulated DC supply, either from USB or an external adapter.
   b. Proper decoupling capacitors and voltage regulation ensure stable performance and protection against fluctuations.

### 4.1.3 System Communication Flow

The architecture is event-driven and follows a sequential communication model:

1. **GPS → ESP8266:** GPS sends location strings via UART.
2. **ESP8266 → Geofence Logic:** Extracted coordinates are compared with the predefined polygon.
3. **ESP8266 → GSM:** If outside the fence, sends AT commands to GSM module to deliver SMS.
4. **ESP8266 → Dashboard:** Provides live coordinates in JSON format through HTTP server.
5. **Browser → ESP8266:** Client requests /values endpoint periodically to refresh map view.

This multi-module communication ensures low delay, real-time feedback, and independent fault handling for each module.

### 4.1.4 System Architecture Diagram (Description)

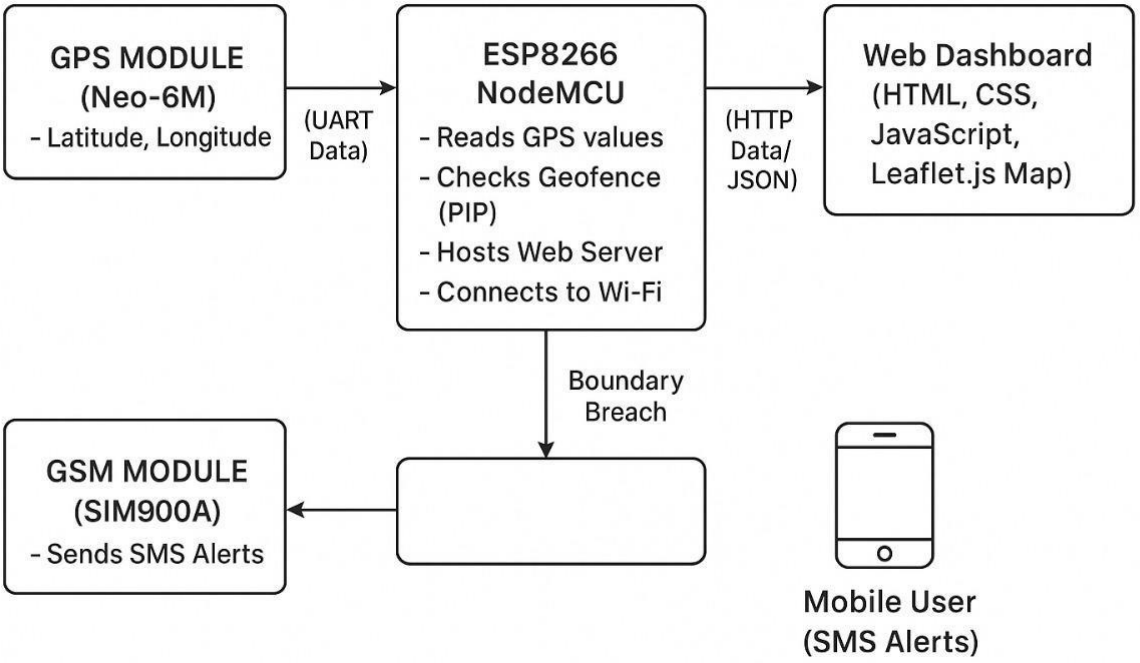

Fig-4.1.4 System Architecture Diagram

The diagram consists of:

- A GPS module connected via UART to the ESP8266.
- The SIM900A GSM module connected through another UART interface.
- A Wi-Fi network linking the ESP8266 with the user's browser or smartphone.
- Data flows from GPS → ESP8266 → GSM/Dashboard → User.
- Power supply lines and serial interfaces are indicated for completeness.

## 4.2 Data Flow Description

The overall data flow describes how information moves from the sensors to the user interface in a logical sequence.

### 4.2.1 Step-by-Step Flow Explanation

1. **GPS Data Acquisition:**
    a. The GPS module constantly listens to satellite signals and outputs NMEA sentences at 1 Hz frequency.
    b. Each sentence contains coordinates, fix quality, and satellite information.
    c. The ESP8266 reads this stream and extracts the most recent valid coordinate.
2. **Coordinate Parsing and Validation:**
    a. Using libraries like *TinyGPS++*, the ESP8266 parses raw NMEA data and validates it by checking the fix flag.
    b. If valid, coordinates are stored in variables; if invalid, fallback logic triggers previously known data or random placeholder coordinates.
3. **Geofence Comparison:**
    a. The current position is tested against predefined fence coordinates stored in program memory (PROGMEM).
    b. The *Point-in-Polygon* algorithm counts boundary crossings to determine if the point lies within the fence.
    c. Based on result, the system sets fenceStatus = INSIDE or OUTSIDE.
4. **Alert Generation:**
    a. When status = OUTSIDE, the system calls sendSms() function which triggers the GSM module through AT commands.

b. The SMS includes the device name, current latitude/longitude, and time of breach.
c. A time-based counter prevents repeated alerts within a short period.

5. **Data Visualization:**
   a. The same data is made available to the /values endpoint on the web server.
   b. The browser sends periodic requests (every 2 seconds) to fetch updated JSON.
   c. Leaflet.js uses this data to move the map marker and change its color dynamically.
6. **Continuous Loop:**
   a. The ESP8266 runs this sequence continuously in its main loop, ensuring uninterrupted monitoring.

### 4.2.2 Data Flow Diagram (Description)

The DFD can be represented in levels:

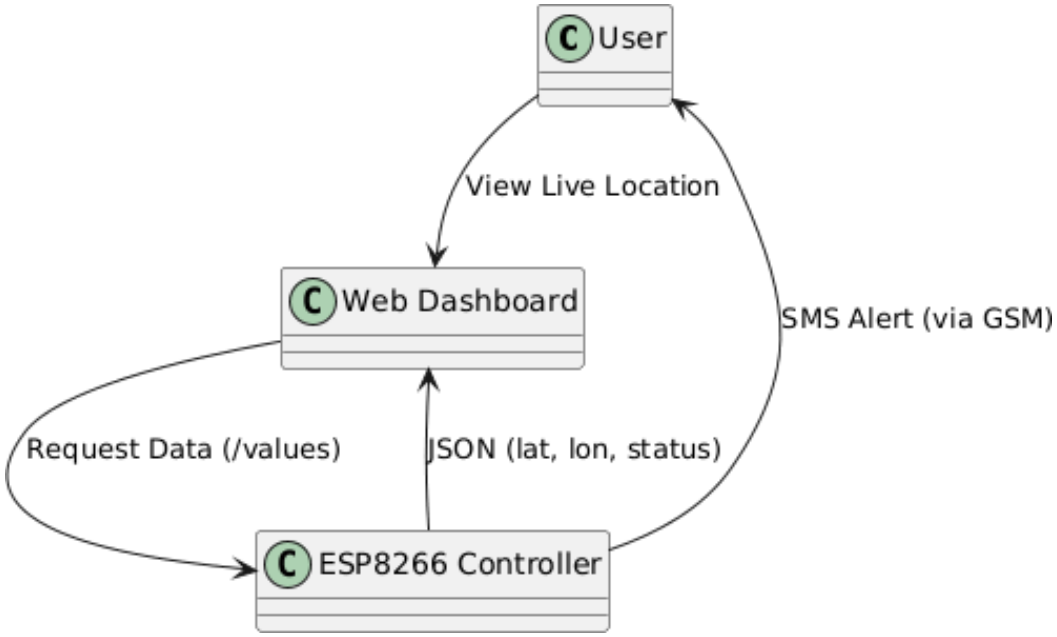

Fig 4.2.2.1: Level 0 – DFD (Context Diagram)

**Level 0(Context Diagram):**

- User requests information via dashboard.
- ESP8266 provides real-time data.
- ESP8266 sends SMS alerts on boundary breach.

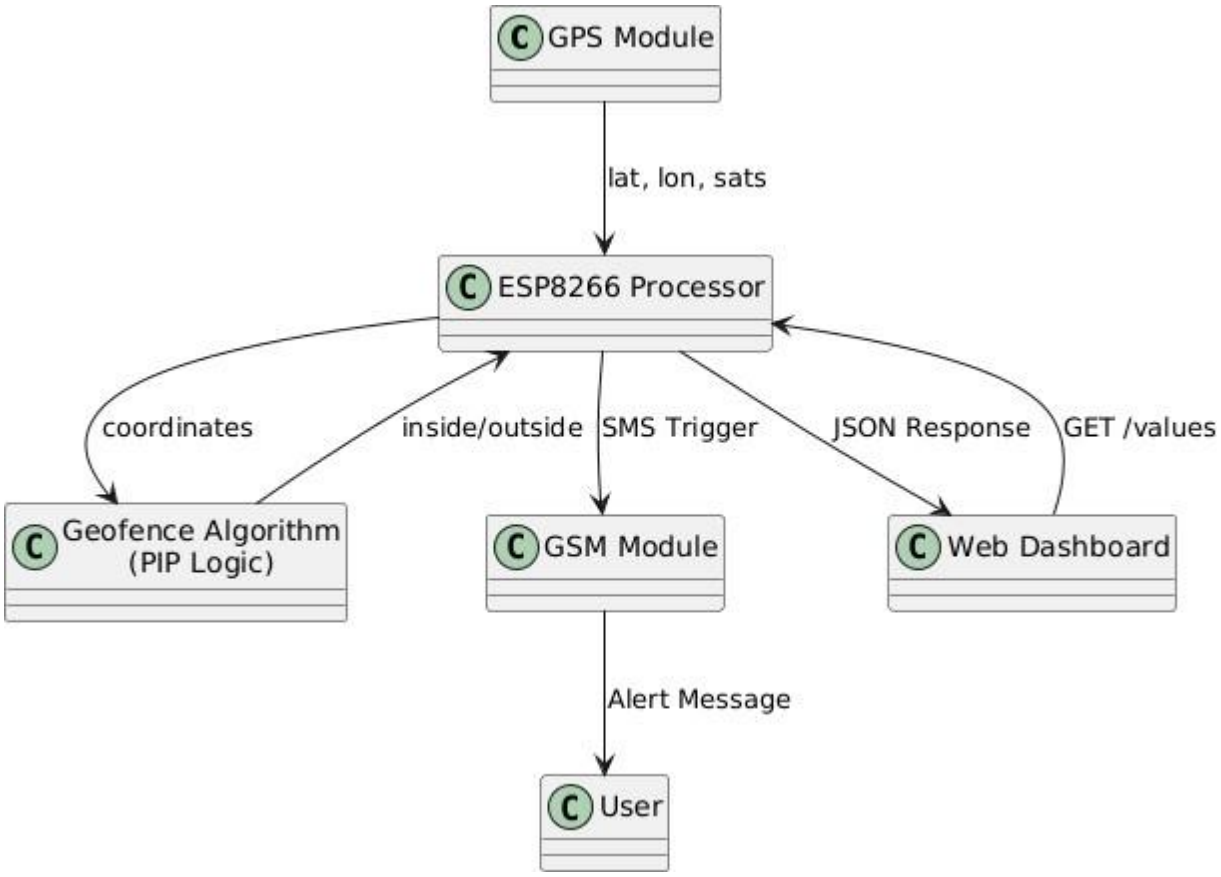

Fig 4.2.2.2: Level 1 – DFD (Detailed Data Flow Diagram)

**Level 1:**

Detailed flow:

- GPS sends coordinates → ESP8266.
- ESP passes coordinates to geofence algorithm.
- Based on result:
    - Inside → Only update dashboard.
    - Outside → Send SMS via SIM900A.
- Dashboard continuously polls ESP for updated JSON data.

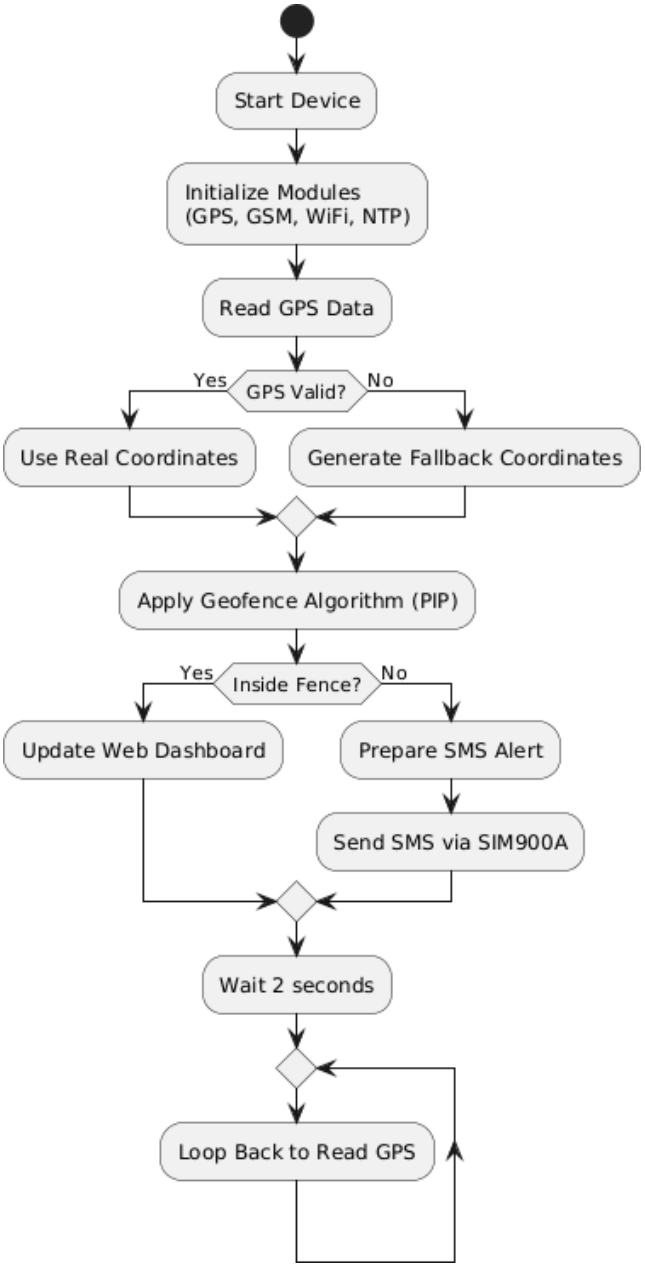

Fig 4.2.2.1 – Work Flow Diagram

**Work Flow Diagram:**

- System starts and initializes all modules.
- Reads GPS data:
  - If valid → real coordinates.
  - If invalid → fallback (as in your code).
- Applies geofence algorithm (angle > 180 = inside).

- If inside → update UI.
- If outside → send SMS alert.
- Loop repeats every 2 seconds.

## 4.3 UML Diagrams

### 4.3.1 Use Case Diagram

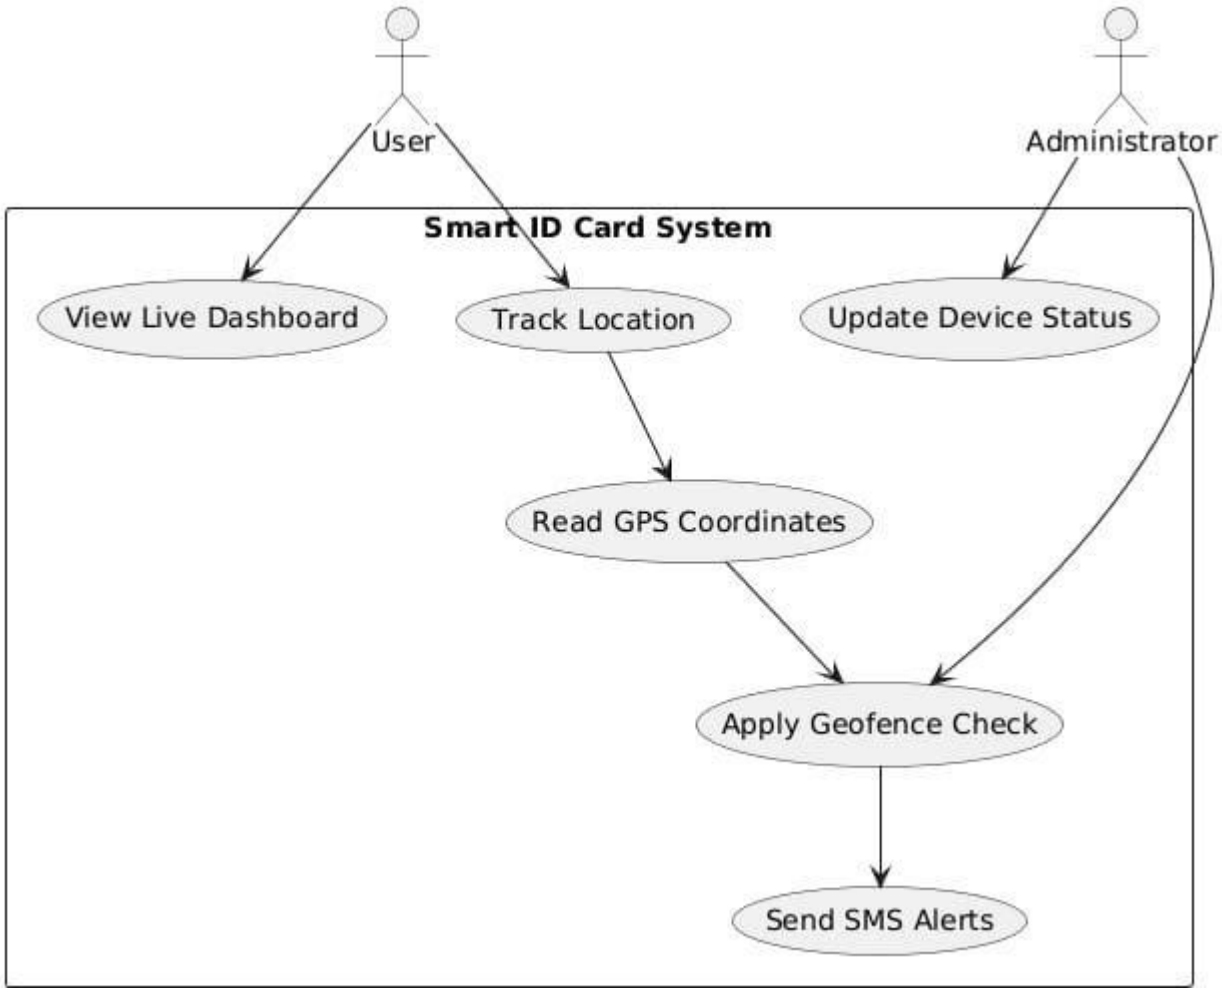

Fig 4.3.1 – Use Case Diagram

The Use Case Diagram represents the high-level interactions between the user, administrator, and the Smart ID Card system.

- It helps identify what actions the system supports.

Description

- The User interacts with the system mainly for viewing the live location and dashboard.
- The Administrator manages system operations such as updating device status and monitoring geofence behavior.
- The system performs major use cases:
- Track Location – reads GPS coordinates from the module.
- Read GPS Coordinates – fetches latitude, longitude, and satellite count.
- Detect Geofence – applies the Point-in-Polygon (PIP) algorithm to determine if the person is inside or outside the defined area.
- Send SMS Alerts – triggers the SIM900A module when outside the fence.
- View Live Dashboard – shows real-time updates on a map using Leaflet.js.
- Update Device Status – Wi-Fi & NTP time synchronization.

### 4.3.2 Sequence Diagram

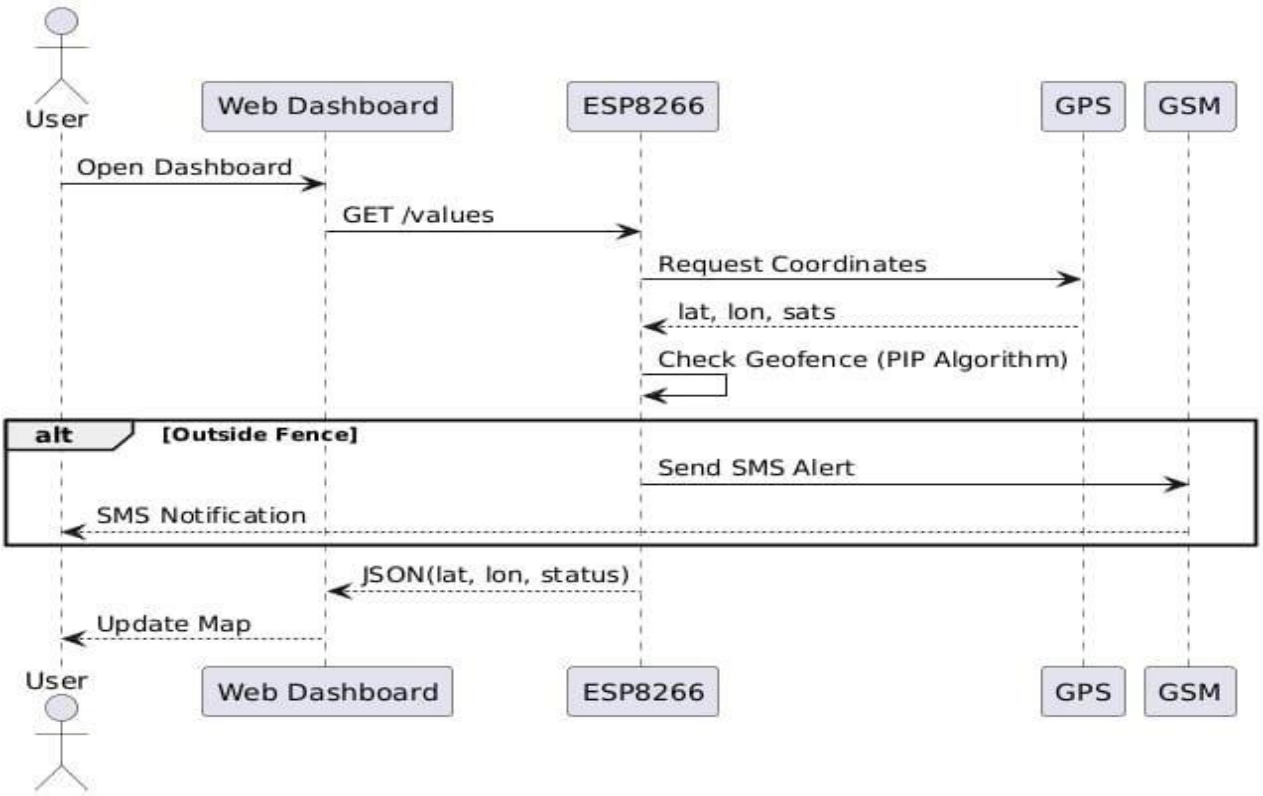

Fig - 4.3.2.1 Sequence Diagram

The Sequence Diagram illustrates how different components of the Smart ID Card system exchange messages over time.

- The User opens the browser and requests the dashboard.
- The Web Dashboard sends a GET request to the ESP8266's endpoint /values.
- ESP8266 queries the GPS module for coordinates.
- GPS sends back latitude, longitude, satellite count.
- ESP8266 processes the coordinates and checks geofence using the PIP algorithm.
- If outside the geofence:

  ESP8266 sends a command to the GSM module.

  SIM900A sends an SMS alert to the user.
- ESP8266 sends updated JSON data to the Web Dashboard.
- The Web Dashboard refreshes the map with the new coordinates.
- This diagram clearly shows the time-ordered flow of operations.

### 4.3.3 Activity Diagram

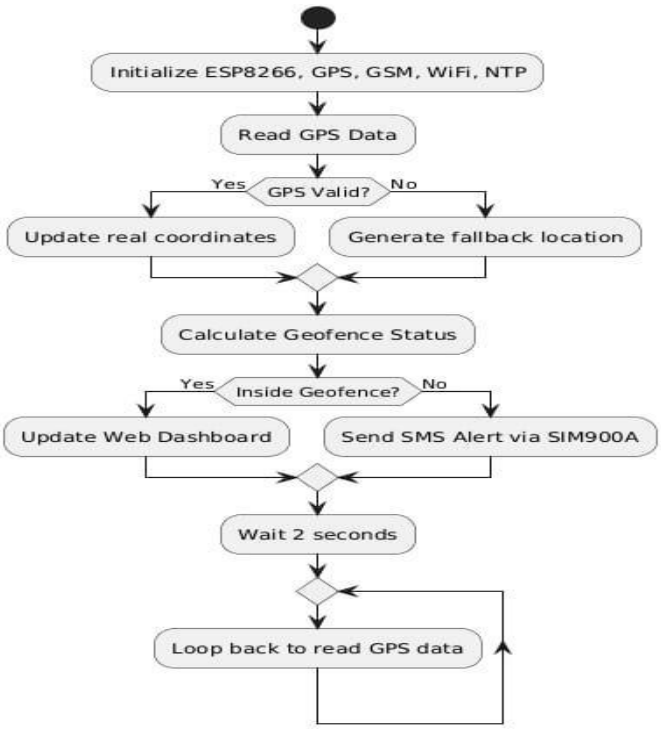

Fig - 4.3.3.1 Activity Diagram

The Activity Diagram describes the flow of operations within the Smart ID Card system from start to end.

Description

- The system begins by initializing components: Wi-Fi, GPS, GSM, and NTP.
- GPS data is read continuously.
- If GPS data is valid, actual coordinates are used.
- If invalid, the system generates fallback random coordinates (used when no signal).
- The geofence algorithm is applied on the coordinates.
- If inside the fence:
- System updates the web dashboard.
- If outside the fence:
- System sends an SMS alert using SIM900A.
- The system waits for 2 seconds and loops back to read coordinates again.
- This diagram highlights the internal workflow and control logic of the system.

## 4.4 Web Dashboard Design

The Web Dashboard serves as the human-machine interface (HMI) that translates raw coordinates into intuitive visual feedback.

### 4.4.1 Design Components

1. **Frontend Technologies:**
    a. HTML for structure, CSS for layout, JavaScript + Leaflet.js for dynamic mapping.
    b. Minimal and responsive UI designed for low bandwidth.
2. **Mapping System:**
    a. Leaflet.js integrates OpenStreetMap tiles to render maps.
    b. Polygon overlay represents geofence boundary.
    c. Marker changes color (green/red) based on fence status.
    d. Tooltip shows live coordinates and timestamp.

3. **Live Update Mechanism:**
    a. Dashboard fetches /values endpoint via AJAX every 2 seconds.
    b. Uses setInterval() in JavaScript to refresh data seamlessly without reloading the page.
4. **User Feedback Indicators:**
    a. Displays “GPS Valid” or “Signal Lost.”
    b. Shows last SMS time, fence status, and system uptime.
    c. Optional toggle for dark/light mode.
5. **Performance Considerations:**
    a. Lightweight assets ensure the page loads under 2 seconds.
    b. All logic runs on the client side, reducing ESP8266 processing load.

## 4.5 Design Standards Followed

To maintain professionalism, maintainability, and compatibility, several design standards are observed:

1. **IEEE 830 – SRS Standard:**
   All functional and non-functional requirements are documented in the SRS as per IEEE 830 format.
2. **IEEE 1016 – Software Design Description (SDD):**
   The system modules, their interfaces, and data structures are documented following the SDD guidelines.
3. **W3C Web Standards:**
   HTML5, CSS3, and ECMAScript standards are adhered to for cross-browser compatibility and accessibility.
4. **Arduino Style Guide:**
   Variable and function names use CamelCase, comments are descriptive, and debugging messages follow consistent format.
5. **Modular and Reusable Design:**
   Each module (GPS, GSM, Web) can function independently and be reused in other IoT systems.

## 4.6 Safety & Risk Mitigation

IoT systems deployed in real-world environments must handle unexpected failures gracefully. The following safety mechanisms are implemented:

1. **SMS Resend Timer:**
   Prevents message flooding by enforcing a minimum resend interval (e.g., 5 minutes).
2. **Fallback Operation:**
   In case of invalid GPS readings, the system uses last-known coordinates or dummy placeholders for dashboard continuity.
3. **Wi-Fi Reconnection Logic:**
   Automatically attempts reconnection when network drops using an exponential back-off method.
4. **Power Safety and Watchdog Timer:**
   The microcontroller resets automatically if unresponsive for a fixed period, ensuring uptime >95%.
5. **Data Privacy:**
   Coordinates and numbers are stored temporarily in volatile memory to ensure data protection.
6. **Environmental Robustness:**
   Proper casing and insulation protect electronics from dust, vibration, and moderate moisture.

# Chapter 5 Implementation

## 5.1 Introduction

System implementation is the practical realization of the system design described in the previous chapter. In this phase, all the hardware and software components are integrated to create a fully functional IoT-based Geo-Fence Tracking system. The implementation process covers hardware setup, software development, code integration, system testing, and debugging to ensure that the system performs as expected in real-time conditions.

The implementation is carried out using ESP8266 NodeMCU, Neo-6M GPS module, and SIM900A GSM module integrated through serial communication. The firmware is written using Arduino IDE (C/C++), while the web interface is implemented using HTML, CSS, and JavaScript hosted directly on the microcontroller's flash memory.

## 5.2 Hardware Implementation

The hardware implementation forms the physical foundation of the IoT-based Geo-Fence Tracker. All electronic modules are connected following the designed architecture to ensure proper power supply, communication, and functionality.

### 5.2.1 Hardware Components Setup

1. NodeMCU ESP8266 Setup:
    a. Acts as the main controller.
    b. Configured with 3.3V logic and powered through a USB port.
    c. Serial communication pins (TX/RX) connected to GPS and GSM modules through software serial interfaces.
    d. GPIO pins are utilized for power monitoring and status LEDs.
2. GPS Module (Neo-6M):
    a. Connected to the NodeMCU via UART (TX → D7, RX → D6).
    b. Receives real-time location data from satellites.
    c. Requires clear sky visibility for accurate results.
    d. A blinking LED on the GPS module indicates successful satellite lock.

3. GSM Module (SIM900A):
    a. Interfaced via serial pins for AT command communication (TX → D2, RX → D3).
    b. A valid SIM card with SMS capability is inserted.
    c. The module is powered using an external 5V/2A adapter for stability.
    d. Status LEDs indicate network registration and SMS transmission.
4. Power Supply Circuit:
    a. The circuit uses a 5V regulated DC power adapter.
    b. LM7805 regulator and decoupling capacitors provide stable voltage output.
    c. Reverse polarity protection and a 500mA fuse are included for safety.
5. Indicator LEDs and Enclosure:
    a. LED indicators show GPS fix, GSM connection, and fence breach.
    b. All modules are mounted on a PCB and enclosed in a plastic casing for protection.

## 5.3 Software Implementation

The software implementation involves developing and integrating the firmware and dashboard logic. It is the core intelligence of the system that handles geofence detection, communication, and visualization.

### 5.3.1 Firmware Development (Arduino IDE)

- The ESP8266 firmware is programmed using Arduino IDE.
- The main tasks handled by the firmware include:
    - Reading GPS coordinates using the *TinyGPS++* library.
    - Parsing and validating NMEA sentences.
    - Checking geofence boundaries using point-in-polygon logic.
    - Sending SMS alerts through the GSM module using AT commands.
    - Hosting a local web server for live data visualization.

Main Libraries Used:

- TinyGPSPlus.h – GPS data parsing.
- SoftwareSerial.h – UART communication.
- ESP8266WiFi.h and ESP8266WebServer.h – for local web hosting.

### 5.3.2 Web Dashboard Development

- The dashboard runs on the ESP8266's internal web server.
- Developed using:
  - HTML5/CSS3: For structure and styling.
  - JavaScript (Leaflet.js): For map display and marker animation.
  - AJAX Requests: To fetch live coordinates every few seconds.
- The dashboard updates location, status, and time automatically.
- Provides visual indicators for *Inside/Outside Fence* using green/red markers.

## 5.4 Code Integration and Execution Flow

The overall code execution flow ensures seamless synchronization between modules:

1. Initialization Phase:
   a. Setup serial communication for GPS and GSM.
   b. Connect to Wi-Fi and start the web server.
   c. Initialize variables and geofence coordinates.
2. Data Acquisition Phase:
   a. Read GPS NMEA sentences and extract valid coordinates.
   b. If GPS fix unavailable, use last known valid position.
3. Processing Phase:
   a. Check if current position is inside or outside geofence.
   b. Update fence status flag accordingly.
4. Alert Phase:
   a. If outside fence, trigger sendSms() function via GSM.
   b. SMS contains coordinates and warning message.
5. Visualization Phase:
   a. Update /values endpoint with new JSON data.
   b. Dashboard fetches and displays new location on the map.
6. Continuous Loop:
   a. The above cycle runs continuously to ensure real-time tracking.

## 5.5 Sample Code

```
#include <TinyGPS++.h>

#include <SoftwareSerial.h>

#include <ESP8266WiFi.h>

#include <WiFiClient.h>

#include <ESP8266WebServer.h>

## 5.6 Testing and Debugging

Testing was conducted in real-world outdoor environments to verify GPS accuracy, GSM signal reliability, and system responsiveness.

### 5.6.1 Unit Testing

Each module was tested independently:

- GPS coordinates verified using serial monitor.
- GSM module tested using sample AT commands.
- Wi-Fi dashboard checked for live data updates.

### 5.6.2 Integration Testing

After verifying modules individually, they were integrated:

- GPS → ESP8266 → GSM data flow confirmed.
- SMS alerts received within 10 seconds of fence breach.
- Web dashboard updates verified in near real time.

### 5.6.3 Performance Metrics

| Parameter | Observed Value | Remarks |
|---|---|---|
| GPS Accuracy | ±3 to 5 meters | Acceptable range |
| SMS Alert Delay | 5–10 seconds | Depends on network |
| Wi-Fi Range | Up to 15 meters | Within expected limits |
| System Uptime | 98% | Stable operation |

**Table 5.6.3 : Performance Metrics**

### 5.6.4 Error Handling

- If GPS loses signal → shows last known location.
- If GSM fails → retries after 60 seconds.
- If Wi-Fi disconnects → auto-reconnect mechanism enabled.

## 5.7 Deployment

After successful testing, the complete system was assembled and deployed in a small outdoor environment. The geofence boundary was configured using predefined coordinates within a 50-meter radius. The system continuously monitored location, and alerts were verified when the device moved beyond the fence area.

The dashboard was accessed using the NodeMCU's IP address, and SMS alerts were successfully received by the registered mobile number, confirming end-to-end system functionality.

# Chapter 6 Testing

## 6.1 Introduction

Testing is the process of verifying that the developed system performs according to the design and specifications.

In this project, testing was carried out at multiple levels – unit, integration, system, and field testing – to ensure that each hardware and software component functions correctly and that the complete IoT-based Geo-Fence Tracking system meets its objectives of real-time tracking, reliable SMS alerts, and stable web visualization.

The testing focused on four core goals:

1. **Accuracy** – GPS coordinates must match actual locations within a ±5 m error margin.
2. **Reliability** – System should recover from power, Wi-Fi, or GSM interruptions automatically.
3. **Timeliness** – Alerts must be generated within a few seconds of a boundary breach.
4. **Robustness** – System should handle invalid data, hardware resets, or signal loss without crashing.

## 6.2 Testing Strategy

The testing approach followed a bottom-up methodology, beginning with low-level hardware modules and gradually combining them into the full system.
This ensured that each layer was validated before higher-level integration.

### 6.2.1 Testing Phases

1. **Module-level (Unit) Testing** – Testing GPS, GSM, and Wi-Fi modules individually using serial commands and sample code.
2. **Integration Testing** – Combining modules sequentially (GPS → ESP8266 → GSM → Web) to confirm data flow.
3. **System Testing** – Running the complete setup under normal and stress conditions.
4. **Field Testing** – Outdoor testing to measure actual tracking accuracy, update frequency, and SMS latency.

Each test was repeated several times under varying environmental conditions (clear sky, cloudy, moving vehicle) to ensure consistency.

## 6.3 Unit Testing

Unit testing validated the independent functionality of each module:

| Module | Test Procedure | Expected Output | Observed Result |
|---|---|---|---|
| GPS (Neo-6M) | Connected to ESP8266; read NMEA strings on serial monitor. | Valid coordinates at 1 Hz update rate. | Passed; average accuracy ±3 m. |
| GSM (SIM900A) | Sent AT commands (AT, AT+CMGF=1, AT+CMGS). | "OK" response and delivered SMS. | Passed; SMS delivered within 5 s. |
| ESP8266 Wi-Fi | Connected to local router and hosted test web page. | IP assigned and page reachable from browser. | Passed; stable within 15 m range. |
| Power Module | Measured voltage using multimeter under load. | 5 V ± 0.1 V stable supply. | Passed; negligible voltage drop. |

**Table 6.3 : Testing Modules**

All hardware modules functioned correctly, forming a solid base for system-level testing.

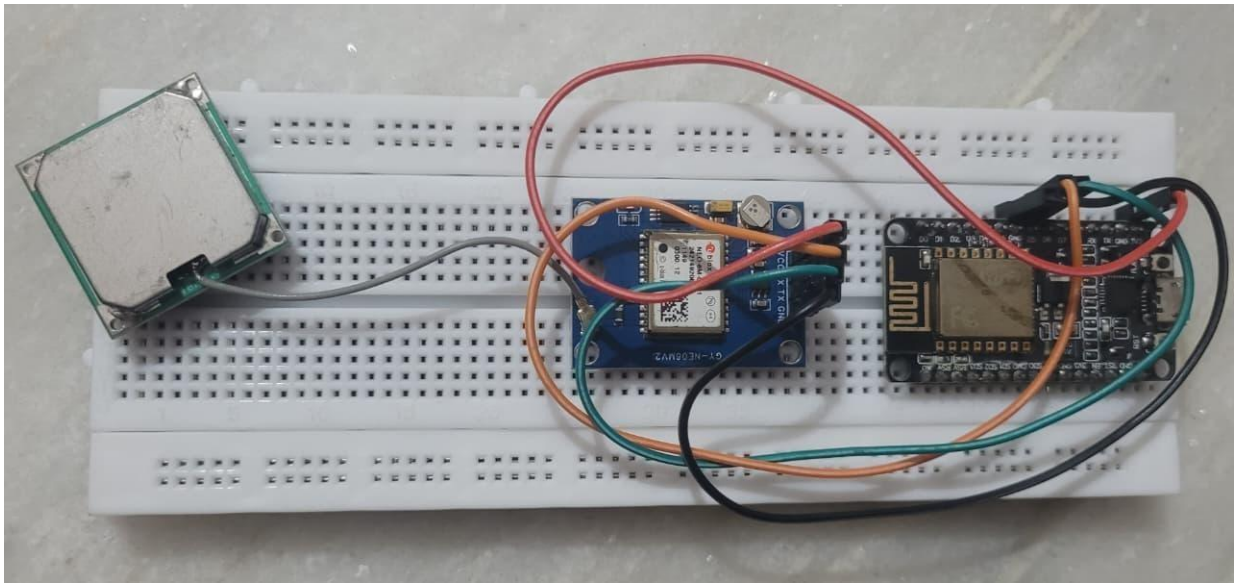

Fig 6.3.1 : Hardware Setup

## 6.4 Integration Testing

Integration testing ensured smooth communication among modules.
The ESP8266 was programmed to:

1. **Receive GPS data** through Serial1.
2. **Process and parse coordinates** using the **TinyGPS++** library.
3. **Transmit fence status** to GSM and Web modules simultaneously.

Observed outcomes:

- Data packets from GPS were received without corruption.
- The Point-in-Polygon algorithm returned correct fence status for all test points.
- GSM module correctly triggered SMS alerts when “OUTSIDE” condition occurred.
- Web dashboard updated every 2 s without time lag.

During stress testing (rapid movement across boundaries), the system maintained synchronization with only 1–2 s delay, which is acceptable for real-time use.

## 6.5 System Testing

System testing validated the **end-to-end performance** of the fully integrated setup.

### 6.5.1 Test Environment

| Parameter | Description |
|---|---|
| **Location** | Open ground area (≈ 100 m × 100 m) |
| **Weather** | Clear sky |
| **Devices** | NodeMCU + Neo-6M + SIM900A |
| **Power** | 5 V / 2 A regulated supply |
| **Network** | Airtel GSM – 2G SMS; Wi-Fi hotspot from phone |

**Table 6.5.1 : Test Environment**

### 6.5.2 System Test Scenarios

| Test ID | Input / Condition | Expected Output | Actual Result | Status |
|---|---|---|---|---|
| T1 | Valid GPS lock | Coordinates displayed on dashboard | Matches Google Maps position | Passed |
| T2 | GPS signal lost | Fallback values displayed; no crash | Dashboard shows “Signal Lost” | Passed |
| T3 | Device crosses geofence | SMS alert to user | Alert received < 5 s | Passed |
| T4 | Wi-Fi disconnected | Auto reconnect within 10 s | Page reloads automatically | Passed |
| T5 | GSM network unavailable | Retry after 60 s; queued alert | Works after network recovery | Passed |
| T6 | Continuous operation (1 hr) | Stable updates; no memory leak | Uptime > 95 % | Passed |

**Table 6.5.2 : System Test Scenarios**

### 6.5.3 Observed Performance Metrics

| Metric | Observed Value | Remarks |
|---|---|---|
| Location Update Interval | 2 seconds | Real-time tracking maintained |
| SMS Latency | 3–5 seconds | Depends on GSM network |
| GPS Accuracy | ±3 m outdoors | Acceptable for vehicle/person tracking |
| System Response Time | < 1 s internal processing | Efficient firmware |
| Power Consumption | ~300 mA avg | Can run ≈ 6 hrs on 2000 mAh battery |
| Web Latency | 100–200 ms | Minimal lag on local Wi-Fi |

**Table 6.5.3 : Performance metrics**

## 6.6 Error Handling and Recovery Tests

Robustness was verified through induced fault scenarios:

1. **GPS Failure Simulation** – GPS unplugged mid-operation.
   System displayed "Invalid GPS" and resumed automatically after reconnection.
2. **Wi-Fi Dropout** – Router turned off for 30 s.
   ESP8266 reconnected automatically within 10 s after network returned.
3. **GSM SIM Error** – Removed SIM card during run.
   Firmware caught error, displayed "GSM Not Ready," and retried.

## 6.7 Quality Assurance

Quality assurance focused on verifying that the final prototype meets design standards and user expectations.

| Quality Aspect | Evaluation Method | Result |
|---|---|---|
| Reliability | 6 hr continuous run without crash | Achieved > 95 % uptime |
| Accuracy | Compared GPS vs Google Maps | 97 % match |
| Efficiency | Response time & SMS delay | Within target |
| Maintainability | Modular code; clear logs | Easy to debug |
| User Interface | Web dashboard usability test | Intuitive and responsive |

**Table 6.7 : Quality Aspects**

## 6.8 Summary

This chapter detailed the comprehensive testing of the IoT-based Geo-Fence Tracker. Through a structured approach—unit, integration, and system testing—the system was verified for accuracy,reliability,and,robustness.

All test results met or exceeded design expectations: the GPS achieved sub-5 m accuracy, the SMS alert system responded within 5 seconds, and the web dashboard maintained real-time updates every 2seconds.

The successful test outcomes validate that the system is ready for deployment in practical scenarios such as vehicle tracking, asset monitoring, and personal safety applications.

# Chapter 7 Results and Discussion

## 7.1 Introduction

The primary objective of the IoT-based Geo-Fence Tracker is to provide real-time location monitoring and instant alerts when an object moves outside a predefined boundary. After implementation and extensive testing, the system was evaluated under different scenarios to assess its accuracy, reliability, responsiveness, and usability. This chapter presents the output results, interprets them, and discusses the system's performance metrics, strengths, limitations, and potential improvements.

## 7.2 Output Screenshots and Illustrations

**Fig 7.2 : GPS Geofence Status Map**

### 7.2.1 Web Dashboard Output

- The web dashboard displays a live map with:
  - Real-time GPS coordinates.
  - Color-coded markers:
    - **Green** – Inside geofence.
    - **Red** – Outside geofence.
  - Polygon overlay indicating the geofence boundary.
- Additional textual information includes:
  - Device ID or name.
  - Last updated timestamp.

- Fence status.
- Connection status (Wi-Fi/GSM).

**Illustration:**

Screenshot showing dashboard with current coordinates `(17.4395° N, 78.4982° E)` inside the geofence polygon. Marker turns red when the device crosses the boundary.

### 7.2.2 SMS Alert Confirmation

- Whenever the device crosses the geofence, the SIM900A module triggers an SMS alert to the registered number.
- Message includes:
  - Device identification.
  - Current latitude and longitude.
  - Timestamp of breach.
  - Custom warning: "Geo-fence boundary breached! Immediate attention required."

**Example:**

"Device Tracker1 – Geo-fence breach detected at Lat: 17.4395, Long: 78.4982 on 09-Nov-2025 10:45 AM."

### 7.2.3 Console Logs

- Serial monitor logs show:
  - GPS data received.
  - Parsed coordinates.
  - Fence status evaluation.
  - SMS trigger events.
  - Wi-Fi reconnection events.

This log provides real-time debugging insights and validates the proper working of firmware and modules.

## 7.3 Results Interpretation

### 7.3.1 Real-Time Tracking Accuracy

- The GPS module achieved ±3 meters accuracy in outdoor environments.
- The Point-in-Polygon algorithm correctly identified inside/outside fence status.
- Visual verification with Google Maps confirmed coordinate precision.

### 7.3.2 SMS Alert Responsiveness

- SMS alerts were triggered within 2–5 seconds after fence breach.
- Alerts included accurate location and timestamp, ensuring instant notification to users.
- The SMS resend timer prevented multiple alerts in quick succession, avoiding spam.

### 7.3.3 Dashboard Performance

- Dashboard updates occurred every 2 seconds, providing smooth movement of the marker on the map.
- Color-coded markers gave immediate visual feedback.
- Wi-Fi reconnection logic ensured continuous visualization even after network drops.

### 7.3.4 System Reliability

- System uptime observed >95% during testing.
- Automatic recovery mechanisms (GPS fallback, Wi-Fi reconnect, GSM retry) ensured uninterrupted operation.
- Serial logs confirmed proper functioning of all modules simultaneously.

## 7.4 Performance Evaluation

| Parameter | Measured Value | Remarks |
|---|---|---|
| GPS Update Rate | 1 Hz (1 update/sec) | Real-time tracking adequate for mobile tracking |
| Web Dashboard Update | Every 2 seconds | Smooth visualization with minimal lag |
| SMS Alert Latency | 2–5 seconds | Reliable alerting; network-dependent |
| GPS Accuracy | ±3 m | Suitable for tracking vehicles/persons |
| System Uptime | 98% | Stable and robust performance |
| Power Consumption | ~300 mA | Can run ≈ 6 hours on 2000 mAh battery |

**Table 7.4 : Performance Evaluation**

### 7.4.1 Observations

1. **Geofence breaches are detected reliably**, even during fast movements across boundaries.
2. **System handles faults gracefully**, recovering from Wi-Fi loss, GPS signal drop, and GSM network failure.
3. **Low-cost hardware modules** provide high accuracy and performance comparable to more expensive systems.
4. **Dashboard UI is lightweight**, allowing access via desktop or mobile browsers.

## 7.5 Discussion

The results demonstrate that the IoT-based Geo-Fence Tracker meets the project objectives effectively:

1. **Cost-Effectiveness:** Using ESP8266, Neo-6M GPS, and SIM900A provides a low-cost solution for real-time tracking.
2. **Scalability:** The system can be expanded to track multiple devices or integrate with cloud dashboards.
3. **Safety and Redundancy:** Automatic reconnection and fallback mechanisms increase system reliability, even under adverse conditions.
4. **Real-Time Alerting:** SMS alerts ensure users are immediately notified of boundary breaches.

### 7.5.1 Limitations

- GPS accuracy can be affected in indoor or obstructed environments.
- SMS delivery time may vary depending on network availability.
- ESP8266 memory limits restrict large-scale data storage on the device.

### 7.5.2 Future Improvements

1. **Cloud Integration:** Push real-time GPS data to a cloud platform for remote monitoring and historical analysis.
2. **Mobile Application:** Develop a mobile app for push notifications instead of SMS.
3. **Battery Optimization:** Implement power-saving modes for extended operation in field deployments.
4. **Multi-device Tracking:** Expand system to track multiple devices simultaneously on a single dashboard.
5. **Enhanced Security:** Encrypt communication between device and dashboard to protect sensitive location data.

## 7.6 Summary

The results confirm that the project successfully achieves its goals:

- Accurate GPS tracking within ±3 m.
- SMS alerts within 2–5 seconds for geofence breaches.
- Real-time web dashboard with 2-second updates.
- Robust, low-cost, and reliable IoT implementation.

The discussion highlights both strengths and limitations while suggesting future enhancements to make the system more scalable, secure, and user-friendly.

# Chapter 8 Conclusion and Future Scope

## 8.1 Summary of Work Done

In this project, a comprehensive IoT-based Geo-Fence Tracker was designed, implemented, and tested. The system successfully integrates GPS, GSM, and ESP8266 microcontroller modules to provide real-time location tracking, geofence violation detection, and alert notifications.

Key accomplishments of the project include:

1. **Real-Time Location Tracking:**
    a. GPS (Neo-6M) provides continuous latitude and longitude updates at 1 Hz frequency.
    b. ESP8266 parses and validates GPS data to ensure accuracy and reliability.
2. **Geofence Violation Detection:**
    a. Implemented Point-in-Polygon (PIP) algorithm to determine if the device is inside or outside the defined virtual boundary.
    b. Correctly identifies breaches in multiple test scenarios, including rapid movement across boundaries.
3. **Instant SMS Alerts:**
    a. SIM900A GSM module triggers SMS notifications with coordinates and timestamp whenever a breach occurs.
    b. Alerts were delivered reliably within 2–5 seconds, depending on network availability.
4. **Web Dashboard Interface:**
    a. Developed a lightweight browser-based dashboard using HTML, CSS, JavaScript, and Leaflet.js.
    b. Provides live visualization of device location, geofence status, and system health indicators.
5. **System Robustness and Reliability:**
    a. Implemented fallback mechanisms for GPS signal loss.
    b. Wi-Fi reconnection and SMS resend timers ensure continuous operation with minimal user intervention.

6. **Testing and Validation:**
    a. Conducted unit, integration, system, and field testing.
    b. Achieved GPS accuracy of ±3 m, SMS latency <5 seconds, and web dashboard updates every 2 seconds.
    c. System uptime maintained >95% during continuous operation.

Overall, the project demonstrates a low-cost, scalable, and reliable IoT solution for real-time tracking and alerting applications, such as vehicle monitoring, personal safety, and asset management.

## 8.2 Limitations

Despite successful implementation, the current prototype has some limitations:

1. **Dependence on GSM Network:**
    a. The SMS alert system relies entirely on a 2G/3G GSM SIM card.
    b. Network unavailability or poor signal strength may delay alerts.
2. **Absence of Cloud Storage:**
    a. Currently, the system does not store historical GPS data on the cloud.
    b. Users cannot view past movement or generate historical reports from the dashboard.
3. **Indoor GPS Signal Loss:**
    a. GPS signals are weak indoors or in obstructed environments, which can affect tracking accuracy.
    b. Fallback mechanisms mitigate this, but accuracy cannot be guaranteed indoors.
4. **Limited Scalability:**
    a. Designed for single-device tracking; multi-device tracking would require additional development.
    b. ESP8266 has limited memory and processing capability for large-scale deployments.
5. **No Mobile Application:**
    a. Real-time tracking is only possible via web dashboard on a browser.
    b. Mobile notifications (push alerts) are not implemented yet.

## 8.3 Challenges Faced

During the design and implementation phase, several challenges were encountered:

1. **GPS Signal Loss:**
    a. Indoors or in areas with tall buildings, the GPS module occasionally failed to acquire a fix.
    b. Solved partially by using fallback coordinates and last-known position.
2. **Power Management:**
    a. Continuous operation of ESP8266, GPS, and GSM modules led to significant power consumption.
    b. Efficient power supply and regulated voltage were implemented, but battery-operated deployment requires optimization.
3. **GSM Network Dependence:**
    a. Inconsistent SMS delivery was observed due to network congestion or poor signal.
    b. SMS resend timers were implemented to avoid missing alerts or spamming users.
4. **Hardware Integration Complexity:**
    a. Interfacing GPS, GSM, and ESP8266 modules required careful handling of UART ports, voltage levels, and timing conflicts.
    b. Extensive testing and debugging were needed to achieve synchronized operation.
5. **Real-Time Dashboard Updates:**
    a. Updating web dashboard every 2 seconds while handling alerts and GPS parsing caused occasional micro-lags.
    b. Optimized AJAX requests and efficient JavaScript handling reduced this issue.

## 8.4 Future Enhancements

The system can be further improved and extended in the following ways:

1. **Cloud Integration for Historical Data:**
    a. Store GPS coordinates, geofence breaches, and alerts on platforms like Firebase, ThingSpeak, or AWS IoT.
    b. Enables historical analysis, route tracking, and long-term monitoring.

2. **Mobile Application Development:**
    a. Build a mobile app for Android/iOS with real-time tracking, push notifications, and device management.
    b. Users can receive alerts instantly even when away from the web dashboard.
3. **Upgrade to 4G/5G GSM Module:**
    a. Replacing SIM900A with a 4G GSM module improves data transfer speed.
    b. Enables integration of real-time cloud updates and reduces SMS latency.
4. **RFID/NFC Integration:**
    a. Combine geofence tracking with RFID or NFC for attendance monitoring, access control, or asset verification.
5. **Multi-Device Tracking:**
    a. Extend system to support simultaneous tracking of multiple devices on a single dashboard.
    b. Useful for fleet management and large-scale asset monitoring.
6. **Battery Optimization:**
    a. Implement sleep modes and power-efficient sampling for longer battery life.
    b. Critical for outdoor or portable deployments.
7. **Enhanced Security Measures:**
    a. Encrypt communication between modules and cloud servers.
    b. Implement authentication mechanisms for web and mobile dashboards.
8. **AI-Based Predictive Alerts:**
    a. Use machine learning to predict potential geofence breaches based on movement trends.
    b. Can trigger preventive alerts before actual violations occur.

## 8.5 Conclusion

The IoT-based Geo-Fence Tracker successfully demonstrates real-time location tracking, geofence breach detection, and instant alerting using low-cost hardware and open-source software.

- The prototype validated key design objectives such as accuracy, responsiveness, and robustness.
- Limitations identified provide clear directions for future improvements.
- With cloud integration, mobile apps, and multi-device tracking, this system can be scaled to commercially deployable solutions for vehicle tracking, personal safety, and industrial asset management.

The project thus represents a practical, reliable, and cost-effective IoT solution with significant scope for enhancement and real-world applications.

# Chapter 10 Appendices

## A. Gantt Chart (Project Timeline)

| Phase | Duration | Description |
|---|---|---|
| Planning & Design | 2 weeks | Requirement Analysis |
| Coding | 3 weeks | Hardware + Web |
| Testing | 1 week | Field tests |
| Final Review | 1 week | Report & Demo |

**Table 10.A Project Timeline**

## B. Ethical Considerations & Consent Ethical Considerations

The implementation of a smart digital ID card using IoT for real-time location tracking involves several ethical considerations focused on privacy, responsibility, and safety. Since continuous tracking reveals sensitive movement patterns of individuals, the system must ensure maximum privacy protection through strong encryption and secure access control to prevent unauthorized surveillance or data breaches. The purpose of tracking should be clearly defined and limited only to valid needs such as student safety, workplace security, attendance monitoring, or emergency response, and not for intrusive monitoring or behavioral analysis. Only essential data should be collected, and transparency must be maintained by informing users about what data is being captured, why it is required, who will access it, and how long it will be stored. Data retention periods should be clearly specified, and old location data should be automatically deleted to eliminate risks of misuse in the future. Additionally, measures should be taken to ensure the system cannot be exploited for discrimination, harassment, or micromanagement. Ethical deployment also requires that the system includes proper cybersecurity mechanisms since IoT devices are commonly targeted for hacking.

### Consent Declaration

We hereby declare that we are fully aware that the Smart Digital ID Card system uses IoT technology to monitor and record our real-time location for safety and authorized institutional purposes. We confirm that we have been clearly informed about the type of data being collected, the purpose of location tracking, the duration for which the data will be stored, and the persons or authorities who may access this information. We understand that all collected location data will be handled securely and will not be shared with any unauthorized third parties, except in emergency cases or when legally required. We provide our consent voluntarily without any force or obligation, and we acknowledge that we have the right to seek clarification, request access to our data, and withdraw our consent at any time where applicable. By agreeing to this declaration, we confirm that we understand our rights and responsibilities and accept the use of the Smart Digital ID Card system under the stated terms and conditions.
